GROUND WATER IN ONTARIO  
NORTHERN AREA  
1946-1969

---

INTRODUCTION

This bulletin contains water-well record data for the northern area of the province for the period 1946 to 1969. It is the twelfth publication in which basic data have been published on ground-water conditions in Ontario. Table VI lists the other publications.

The map on page iv shows the four areas into which the province is divided for the publication of these bulletins. Data for the District of Manitoulin which were formerly published with the southwestern area are now included with the northern area.

This bulletin is the first produced from the printout of computer-stored data. The principal changes and other pertinent details are given in the section entitled "Explanation of Column Headings." In keeping with the practice established for previous bulletins, data on climate, observation wells and hydrogeology for the northern area are included in the introductory section.

Enquiries concerning the data in the bulletin should be directed to the Supervisor, Hydrologic Data Section, Water Quantity Branch.

Acknowledgments

The bulletin was prepared by staff of the Hydrologic Data Section who were ably assisted by the Branch EDP liaison officer and staff of the Water and Well Management Section and the Systems and EDP Section.

The assistance and service rendered by the following other persons in making this publication possible is gratefully acknowledged: the water-well boring and drilling contractors who submitted the water-well records; private citizens and personnel of governmental agencies who submitted ground-water levels in the observation well program.

GEOGRAPHY

Topography

The northern area includes all parts of the province north of the previously described southwestern, south-central and southeastern areas. The northern area comprises the following districts:

Algoma	Manitoulin	Parry Sound	Thunder Bay
Cochrane	Muskoka	Rainy River	Timiskaming
Kenora	Nipissing	Sudbury	

The northern area occupies a land area of 304,357\* square miles. The area consists mainly of the Precambrian Shield and the Hudson Bay Lowland. The topography of the Shield area varies from flat, featureless plains to mountainous and rugged terrain which is found near the southern part of the Shield. Some rugged hills are found in the interior, but over much of the Shield, local relief is quite low. The Hudson Bay Lowland is very flat and the only relief is at the banks of the river valleys. The most prominent topographic feature is a low escarpment at the northern limit of the Precambrian exposures. Elevations in the northern area vary from 2,120 feet above sea level at Tip Top Mountain just north of Lake Superior to sea level at Hudson Bay.

\*Compiled from the 1963 Municipal Directory, Ontario Department of Municipal Affairs and Canada Year Book, 1961.

## Climate

The hydrologic characteristics of an area are largely determined by its climate and geology. A proper assessment of the water resources potential of an area requires that observations be made of climatic factors such as precipitation, temperature, wind, and sunshine and the resulting hydrologic events of streamflow and ground-water level fluctuations.

The precipitation data for a number of selected meteorological stations in the northern area for the period 1960-1969 are contained in Table III. The variability of precipitation, which is the input to the ground-water system, affects ground-water levels and ground-water flow. The variability of the monthly and annual precipitation can be observed readily from the data in the table.

## Drainage

The rivers contained in the vast landmass which makes up the northern area have among them the largest rivers in the province. They may be broken into five drainage systems according to their receiving bodies: Ottawa River drainage, Lake Huron including Georgian Bay drainage, Lake Superior drainage, Nelson River drainage and Hudson Bay drainage.

All of these river systems rise in the Precambrian Shield. The Ottawa River and Hudson Bay drainage systems are separated from the Lake Huron and Lake Superior drainage systems by a height of land which is found at an average distance of about 80 miles from the north shores of Lakes Superior and Huron. The Nelson River drainage is separated from the Hudson Bay drainage by a height of land which runs roughly northwest from Graham, Ontario, to Charron Lake in Manitoba.

The rivers are for the most part rock controlled and contain numerous lakes in the Precambrian Shield. It is only those rivers which flow into Hudson Bay and traverse the Hudson Bay Lowland in their lower reaches that have been able to make deep, incised valleys into the unconsolidated deposits down to the Paleozoic bedrock. However, these rivers in the lower reaches are still in various stages of development; they flow through a relatively flat featureless plain that is slowly rebounding from the last ice age.

## HYDROGEOLOGY

In the greater part of the northern area rocks of Precambrian age make up the bedrock. Some of these rocks may be among the oldest on earth. Generally, the Precambrian rocks are divided into early Precambrian as Archean and late Precambrian as Proterozoic rocks.

The early Archean rocks consist mainly of altered volcanic lavas, while later Archean formations consist mainly of sedimentary rocks, such as iron formation, greywacke, slate and conglomerate. Much of the bedrock in the Shield is granitic rocks. The age of these rocks, in many cases, is uncertain.

In many areas the bedrock is composed of Proterozoic rocks which are younger, less altered, and generally less deformed, volcanic and sedimentary rocks. The age of the Proterozoic rocks varies between 1,900 and 570 million years. In the southern part of the area rocks of the relatively young Grenville series, which are made of granitized gneisses, large amounts of crystalline limestone and other highly metamorphosed sediments, extend southwards from a line running from the North Channel of Lake Huron to Lake Timiskaming.

Little is known of the hydrologic characteristics of the Precambrian rocks. Information on the occurrence of ground water is available from limited water-well records and from drilling for the mining industry. Generally, ground water may occur in fractures, joints, cracks, along bedding planes, along fault zones and occasionally in the upper weathered zone of the rock. Fractures or fissures generally diminish with depth. Fault zones, if they are sealed, can be a barrier to ground-water movement.

In a large area adjacent to Hudson Bay, the bedrock is composed of sedimentary rocks of the Paleozoic and Mesozoic eras. The Paleozoic rocks consist of basal sandstones and limestone of Ordovician age, limestones and dolomites of Silurian age, and sandstones, limestones and shales of Devonian age. Most of these formations can be correlated with Paleozoic formations in southern Ontario. Very little is known about the hydrologic characteristics of the Paleozoic formations in northern Ontario. However, since they are stratigraphically similar to rocks in southern Ontario, it is to be expected that their hydrologic characteristics will also be similar.

North of Kapuskasing, mainly in the Mattagami and Missinaibi River area, there is about a 2,500 square mile area where fire clays and micaceous sands with lignite seams of lower Cretaceous age underlie the overburden.

An area of about 50 square miles between Haileybury and Englehart is underlain by Ordovician and Silurian limestones and dolomites. Wells terminating in these rock formations indicate that their water-bearing characteristics are generally good for the development of domestic supplies.

Paleozoic rocks also comprise the bedrock in almost the entire area of Manitoulin Island which covers about 1,500 square miles and is said to be the largest "fresh-water island" in the world. The limestones and dolomites of Ordovician and Silurian age are similar to those found elsewhere in southern Ontario. The unique landform of the Niagara escarpment continues through the island. The Silurian dolomites in the southern two-thirds of the island are generally better water-bearing formations than the Ordovician limestones and dolomites of the northern and northeastern part of the island.

In most of the northern area, the bedrock is covered by unconsolidated materials deposited during the Pleistocene epoch. Most of the overburden deposits were formed by the action of ice, melt water, and in glacial lakes. In the Hudson Bay Lowland area some of the sediments were deposited in a marine environment.

Ground moraines are the most widely distributed glacial deposits and cover mainly the Shield area. They are generally thin and consist of sandy till, up to ten feet in thickness. In some areas the ground moraines are of clayey till, 10 to 15 feet in thickness. In places where drumlins occur, the thickness of the overburden is considerably more. Numerous end moraines consist of sand, gravel and boulders and their thickness may reach 200 feet. Moraines, especially ground moraines, are generally poor sources of ground water, due to their heterogeneous texture.

Glacio-fluvial or meltwater deposits occur in elongated esker complexes, kames and kame moraines, some of which were flattened by wave action of subsequent glacial lakes. The thickness of the esker and kame deposits may be over 100 feet. Outwash deposits are often associated with moraines, kames and eskers, and consist of sand and gravel. Glacio-fluvial deposits, especially if they attain considerable thickness may be excellent aquifers.

Glacio-lacustrine deposits consist of varved clays, fine sand and sand and have generally poor water-yielding characteristics. Glacial Lakes Agassiz and Barlow-Ojibway covered large areas in northern Ontario and deposited fine-grained and some coarser sediments of varying thickness.

Marine clays cover most of the land surface of the Hudson Bay Lowland. These sediments were deposited in the Tyrrell Sea which inundated the area after the last glacier receded. Marine clays are very impervious and are poor aquifers. The marine sediments are underlain by lacustrine sediments and three till sheets in most parts of the area. The lower two till sheets are separated by interglacial sediments of fluvial, lacustrine or marine origin. The average thickness of the drift of the Lowland may be in excess of 40 feet with a probable maximum of 700 feet which has been reported between the Mattagami and Missinaibi Rivers. Recent deposits of peat and muck cover many depressions and low lying areas.

## GROUND WATER

### Occurrence and Source

Ground water is the water that occurs below the surface of the ground in the zone of saturation, where all pore spaces and fractures are filled with water. The surface of the saturated zone is called the water table. A formation that will hold, transmit and yield ground water in usable quantities is known as an aquifer.

Precipitation in the form of rain and snow is the main source of ground water. In general, approximately forty per cent of all precipitation becomes surface runoff and ground water. The rest is returned to the atmosphere by evaporation from the soil and open bodies of water, and by transpiration from vegetation. The range of annual precipitation in the northern area varies very widely. In areas along the north shore of Georgian Bay and in the vicinity of Parry Sound it is as high as 38 inches. In general the annual precipitation decreases from about 30 inches in the southeast to less than 20 inches in the northwest. Precipitation data for a large portion of the northern area are very scant.

Numerous factors, such as the amount and intensity of rainfall, nature of soil and vegetation, slope of land surface, and wind and temperature conditions, govern the portion of precipitation that becomes ground water. In sandy areas the rate of infiltration is higher than in clay areas and the amount of water available for ground-water recharge is correspondingly greater. Before large withdrawals of ground water are planned in an area, a reliable estimate should be made of the average perennial recharge of the aquifer. If this is done, the depletion of ground water stored in aquifers can usually be avoided, and pumping installations can be designed for long economical use.

The amount of water that can be extracted in any area depends on the character of the aquifer and the amount of recharge. Fine-grained materials such as clay or silt have high porosities and abilities to hold large quantities of water in storage but they have low permeabilities which hinder the movement of water through them and make them poor sources of supply. Wells developed in such materials do not meet normal household requirements adequately. Coarse sediments, such as coarse sands and gravels, have high permeabilities and are usually very good sources of ground water.

At the end of 1969 there were 84 municipalities with public water supply systems in the northern area. Of these 24 obtained their supplies from ground sources and 6 relied on both ground-water and surface-water sources.

## Regional Aquifer Characteristics

The general water-bearing characteristics of the different geologic formations of the northern area were discussed in the section dealing with hydrogeology. Because of the vast extent of the area and inaccessibility of large parts and also the very limited drilling information available very few comments can be made about the availability of ground water in the different areas. At the end of 1969 there were over 11,000 recorded wells in the northern area. The majority of wells (over 8,000) terminated in the bedrock, while about 3,000 of the wells obtained water from the overburden and nearly 700 of the wells were reported as dry.

Overburden wells comprise the majority of the wells in the Districts of Algoma and Rainy River while in the Districts of Nipissing and Parry Sound rock wells are predominant.

### Surveys and Investigations

The Commission's activities in ground water surveys and investigations in the northern area up to 1959 are described in earlier bulletins which covered the years up to and including 1959. Activities for the period 1960 to 1969 included contributions to district water resources surveys, special investigations, hydrogeologic surveys undertaken chiefly for municipalities, and supervision at Commission test-drilling and well-construction projects. These are described briefly below:

a) District and Regional Water Resources Surveys - Water resources surveys were undertaken in the District of Sudbury, in the Lakehead area and in the drainage basins of the Upper and Lower Albany, the Attawapiskat, the Severn and the Winisk Rivers.

b) Special Investigations - A number of investigations were carried out involving supervision of pumping tests on non-Commission projects; short surveys for better water supplies for industries, institutions and communities; and water-level interference problems. Some of the major ground-water level interference investigations occurred in the Improvement District of Beardmore; in the Townships of Fisher, Johnson, Marter, O'Brien, Oliver, and Stephenson; in the Town of Kapuskasing; and in the City of Sault Ste. Marie.

c) Hydrogeologic Surveys - Ground-water surveys involving field investigations and reviews of ground-water conditions were undertaken for thirty-five municipalities. The larger municipalities involved were: the Cities of Sault Ste. Marie, and Sudbury; the Towns of Bruce Mines, Hearst, Latchford, and Webbwood; the Townships of Blezard, Calvert, Chapleau, Coleman, Drury, Denison and Graham, Emo, Fauquier, Jaffray and Melick, Machin (Vermilion Bay), McDougall, North Himsforth, Oliver, Rayside, Shackleton and Machin, Shuniah, and Waters.

d) Test-Drilling and Well-Construction Projects - The Commission was active in sixteen test-drilling and well-construction projects in the Towns of Bruce Mines and Webbwood; in the Village of Sundridge; in the Townships of Blezard, Bucke, Chapleau, Emo, Fauquier, Machin (Vermilion Bay), McDougall, Ratter and Dunnett, and Rayside; in the Improvement Districts of Beardmore, and Val Albert; in the townsite of Brunetville, and in the community of Callander. Test drilling was successful and municipal wells were constructed in Callander and in the Townships of Fauquier, McDougall, Ratter and Dunnett; however, sufficient ground-water supplies were not encountered in Beardmore, Bruce Mines, Sundridge, Vermilion Bay and Webbwood; nor in the Townships of Bucke, Chapleau, Emo, and Rayside. Test drilling located sites in the Improvement District of Val Albert where the Town of Kapuskasing later constructed municipal wells.

A number of other agencies carried out studies in the fields of ground water and Pleistocene geology and published reports containing ground-water or other related geological information for areas in northern Ontario during the period 1960 to 1969. A summary of the activities of these agencies follows below:

The Geological Survey of Canada published reports dealing with the surficial geology of the Timiskaming and Cochrane Districts; Red Lake-Lansdowne House and Kirkland Lake area; the Pleistocene palynology and stratigraphy in the area between the lower Great Lakes and James Bay; the glacial history and stratigraphy of the Hudson Bay Lowland; the deglaciation and post glacial events in Ontario between Lake Erie and James Bay; post glacial shoreline features in the northern Lake Huron basin; post glacial uplift studies north of the Huron basin and Lake Huron; a preliminary report on borings through Pleistocene deposits of the Cochrane District and several reports dealing with Paleozoic bedrock geology in parts of northern Ontario.

The Ontario Department of Mines also published numerous reports and maps on bedrock geology, and in many cases commented on the nature of the overburden of areas in northern Ontario.

Officers of the Ontario Department of Lands and Forests studied and compiled data on the surficial geology of the Kenora, Rainy River, Thunder Bay, Algoma, Cochrane, Sudbury, Timiskaming, and Nipissing areas.

The Proceedings of the Geological Association of Canada contained articles on the glacial history of part of northwestern Ontario and on correlation of raised beaches in the Sault Ste. Marie area, Manitoulin Island and Georgian Bay. The Proceedings of the First International Symposium on Arctic Geology and the publication, Canadian Geography, had articles on permafrost investigations in northern Ontario. The Royal Society of Canada Special Bulletin published an article on the soils of the Lake Agassiz region. The Canadian Journal of Earth Sciences published an article on the glacial history of northeastern Ontario and the Cochrane-Hearst area. A publication entitled Life, Land and Water by the University of Manitoba Press published an article on the geology of the glacial Lake Agassiz. An unpublished Ph. D. thesis at the University of Michigan dealt with ground-water flow in the clay belt of northern Ontario and a Ph. D. thesis at the University of Syracuse described the Quaternary geology of the North Bay-Mattawa area, and some publications in the National Museum of Canada Bulletin had articles describing bogs and peatlands in parts of northern Ontario.

The Ontario Department of Highways and several private firms carried out numerous soil and foundation investigations along highways, bridge sites and building sites in the northern area. The reports for most of these investigations contain details of the geologic and ground-water conditions at the test sites. Copies of soil investigation reports on several government projects are on file with the Ministry of the Environment.

The Ontario Water Resources Commission commenced a ten year study of surface and ground-water resources of the James Bay-Hudson Bay Drainage Basin in northern Ontario in 1966.

## WATER WELLS

Most wells are constructed to obtain potable water but some are constructed for other purposes, such as to find and test aquifers suitable for the construction of high capacity wells; to measure changes of ground-water levels or changes in ground-water quality; and to recharge aquifers.

There are many methods of constructing wells. The selection of the best method depends on the character of formations to be penetrated, the proposed use of the well, the diameter and depth, the quantity of water required, and economic considerations. Proper investigations to determine the correct selection of materials and sizes of well components, and good, well-construction practices are worthwhile investments in the development of wells.

Water supplies from shallow aquifers can be extracted by dug, bored, drilled, driven, or jetted wells. Shallow overburden wells are generally dug or bored and are important where only poor quality water is obtainable at depth or where other aquifers with potable supplies are deep, and drilling is very costly. They generally have large diameters which provide storage capacity for water percolating slowly into the wells from formations of poor permeability.

Water supplies from deep aquifers in the overburden or bedrock can be developed most readily by wells drilled by cable tool, hydraulic rotary, air rotary, reverse rotary, or percussion methods. As a general rule, drilled wells which reach deeper aquifers are less affected by seasonal variations in precipitation and usually provide a more dependable water supply.

Improperly constructed wells may become contaminated by the entry of surface drainage through the well cover or cribbing near the top, or through cracks or openings in the casing. All wells should be constructed to prevent surface water getting into them as the effects of pollution of a single well could be widespread. In addition to using water-tight materials, the well top should be raised above the ground surface and the ground should be sloped away from the well. The surface seal and other parts of a well should be checked at regular intervals to ensure that they are effective in safeguarding the supply.

All wells should be tested periodically for bacteria. Water samples for bacterial analyses should be sent to the nearest regional laboratory of the Ontario Department of Health.

On March 29, 1961, section 28a of the Ontario Water Resources Act was enacted to introduce needed control and to promote efficient development and use of ground and surface water. With a few exceptions, a permit is required for the taking of more than 10,000 gallons of water in a day from any ground or surface source of water supply.

A permit is not required for the taking of water for domestic and farm uses as defined, or for fire-fighting purposes, or for taking from a well constructed prior to March 29, 1961, even though the pumping equipment was installed after that date.

A taking of less than 10,000 gallons in a day or a taking by means of permanent works installed prior to March 29, 1961, may, upon notice, require authorization by permit if the taking interferes with any public or private ground water use.

A permit is required for the taking of water for irrigation, municipal, commercial, industrial, recreational and aesthetic use, for de-watering quarries and gravel pits, and foundation sites. Wells used for municipal and/or other public water supplies come under the jurisdiction of the Ministry of the Environment.

Good management of ground water depends on knowledge of the fluctuations of ground-water levels. Water shortages and complaints of well interference can be better understood or resolved by having reliable data on ground-water fluctuations.

The water level measured in a well when there is no appreciable withdrawal, recovery, or recharge taking place, is referred to as the static level. This level may vary as the result of natural phenomena such as precipitation, seasonal evapotranspiration, changes in atmospheric pressures, ground-water discharge, and from man-made causes such as pumping and artificial recharging. When a well is being pumped, the static level will drop and a new water level which is related to the pumping rate will be established. This new level is the pumping level for that rate of pumping. The water level should rise from the pumping level to the static level if sufficient time elapses between successive pumpings. When the pumping level of a well which is maintaining a normal static level keeps getting lower and lower, deterioration of the well is indicated.

This deterioration could have as its cause a poorly constructed well; no screen in a formation that requires one; the selection of the wrong size of screen; pumping at a higher rate than that recommended for the formation and screen selected; sealing of screen openings or crevices in a rock formation with precipitates of lime or ferruginous scale; deterioration of the screen due to electrolytic or bacterial action.

Successful rehabilitation of wells depends on the correct identification of the causes of the problems, and the availability of an adequate procedure to deal with the problem. Cost and the chance of success require careful consideration before rehabilitation is undertaken.

#### Observation Wells

Observation wells are set up for various reasons: to determine the effect of ground-water withdrawals from an aquifer; to measure the variation of ground-water levels with the changing seasons; to compare water levels in bed-rock and overburden aquifers; to show the effects of natural and artificial recharge on an aquifer. The Ontario Hydro observation wells were set up to study the relation between ground-water levels and water available for hydro-electric generation and the effect of the operation of storage reservoirs on ground-water levels.

The Ministry of the Environment is engaged in the extension and improvement of its observation well network and will co-operate with interested parties who are willing to undertake the measurement of ground-water levels at regular intervals. The number and type of observation wells in operation throughout Ontario in the period 1960 to 1969 are summarized below:

Year	Wells with Automatic Recorders	Wells Measured Manually	Ontario Hydro Wells with Data Available to the OWRC	Total Observation Wells
1960	13	14	18	45
1961	15	13	18	46
1962	15	15	18	48
1963	25	31	18	74
1964	25	48	18	91
1965	32	66	18	116
1966	47	63	18	128
1967	50	80	18	148
1968	57	60	18	135
1969	62	96	18	176

#### Water Level Fluctuations

Five figures have been prepared to illustrate ground-water level fluctuations and some phenomena influencing those fluctuations in selected observation wells.

Figure 1 compares three, ten-year hydrographs: one in southern Ontario and two in northern parts of the Province. Unlike observation wells in the lower latitudes of which No. 38 is typical, with its low water levels in September and October at the end of the growing season, observation wells in the higher latitudes tend to record low water levels in March and April at the end of the winter months. The longer winter season with its much lower average temperatures in the northern latitudes usually prevents ground-water recharge during that part of the year.

Figure 2 is a graphic presentation of monthly and annual precipitation recorded at meteorological stations near the observation wells in Figure 1. It is interesting to notice that heavy precipitation commonly occurred in June, July, and August in all three areas.

Fig. 1 — Seasonal water level variations in observation wells

Fig. 2 — Monthly and annual precipitation recorded at meteorological stations near the observation wells in Fig. 1

Fig. 3 — Hydrographs of two observation wells adjacent to surface water storage at an Ontario Hydro damsite

Fig. 4 — Hydrograph from data recorded at an observation well located at a municipal well site

**Fig. 5**—Effect of Atmospheric Pressure Fluctuations on the Water Level in Observation Well No. 90, Township of North York

Figure 3 has been assembled from hydrographs of two observation wells adjacent to surface water storage at an Ontario Hydro damsite. Here we notice that after January 1956 the ground-water levels in the two aquifers were considerably altered, due to the probable effect of water storage.

Figure 4 has been assembled from a hydrograph prepared from data recorded at an observation well located at a municipal well site in Sault Ste. Marie. We see that the precipitation, which is the source of all water in a well, was considerably above average for the period of record. However, the water levels in the aquifer showed an overall lowering since the influences of the re-charging processes were not as great as those of the pumping of the neighboring municipal wells.

The nature of the effect of atmospheric pressure fluctuations on ground water levels is illustrated for an observation well in southern Ontario. Some water levels in observation well No. 90, an artesian well in the Borough of North York, are shown in Figure 5. An increase in atmospheric pressure causes a lowering of the water level in the observation well. In the figure, the atmospheric pressure was expressed in feet of water for direct comparison between the variations of atmospheric pressure and that of the water level. The ratio of the change in water level to the change in atmospheric pressure is known as the barometric efficiency (B. E.) of the well. It is usually expressed as a percentage. The barometric efficiency can be used for estimating the storage coefficient of a confined aquifer. The effect of barometric pressure is important when precise measurements are being made; in pumping tests it may be necessary to correct for barometric pressure changes. Table IV lists the observation wells measured during 1960 to 1969 and Table V contains the observation well data for the northern area.

#### Licensed Boring and Drilling Contractors 1962-1969

Table II is a list of licensed water-well boring and drilling contractors and the number of wells constructed by each contractor in the northern area in each year from 1962 to 1969. This period was chosen to show which drillers have been active in recent years. The contractors listed may have constructed wells in other areas during this period.

#### Water Well Records

All water-well records forwarded by contractors are on file at the offices of the Ministry of the Environment in Toronto and are available to the public for reference purposes.

Most of the important information from the records has been compiled in this bulletin and summarized in Table I. Most information is essentially as supplied by the driller. Some terms employed by drillers have been altered to conform to a standard list of materials which appears under Material Abbreviations in the section that follows.

The pumping-test rates, reported in gallons per minute, do not necessarily represent the rates at which the wells could continue to supply water for prolonged periods of pumping. Continuous pumping at the stated rates could have resulted in some of the wells being pumped dry, while others may have been capable of being pumped steadily at much higher rates than those carried out during the pumping tests.

Well water intended for use by municipalities or in churches, schools, hotels, and buildings generally occupied by several families or groups of people, was classified as public supply under the "Use" heading. Water used in garages, stores and restaurants was classed as commercial; in factories and dairies as industrial; for greenhouses, market gardens and other crops as irrigation.

Many test holes had no water-data recorded. In most of these holes some water may have been encountered. But as a large supply was being sought, no record was made of water information from formations which were likely to yield a supply far below the required quantity.

## EXPLANATION OF COLUMN HEADINGS

MUNICIPALITY	Municipal names, current at the time of printing, are used in the bulletin. Changes in municipalities are indicated by having the old names appear in brackets after the current names e. g. Elliot Lake Township (McGivern) means that wells listed under this heading are in the former Township of McGivern which is now part of the Township of Elliot Lake. In such cases, the survey descriptions given are for the former municipality.
WELL NO	(Well Number) This is a unique number within the county or district under which it is listed; combined with the county or district number it becomes unique within the province.
UTM EASTING NORTHING	<p>(Universal Transverse Mercator Co-ordinates in Metres) This location system makes use of a square grid, 1000 metres x 1000 metres which is super-imposed on maps of the National Topographic System. The vertical grid lines are called Eastings and the horizontal lines Northings.</p> <p>The Easting represents the distance of a well in an easterly direction from a given north-south reference line. The Easting is the upper figure in the column.</p> <p>The Northing represents the distance of a well in a northerly direction from a given east-west reference line. The Northing is the lower figure in the column.</p> <p>The Eastings and Northings allow the plotting of wells on the National Topographical maps directly from the bulletin. Each map contains an explanation on the use of the co-ordinate system.</p> <p>The wells were plotted on topographic maps from diagrams submitted by the drillers, and the UTM co-ordinates were determined from the plotted locations. Wells drilled after December, 1967, have in most cases been plotted directly on the topographic maps at the time of a field check by Water Well Inspectors; their locations have a greater reliability than the earlier records.</p>
ELEV FEET	(Elevation in Feet) This represents the ground elevation at the well site in feet above mean sea level. The elevations were determined from plotted locations on the National Topographical maps and are therefore related to the accuracy of the locations.

DATE The month and year of well completion are given in this column.

DRILLER The driller's license number is given. Table II is a numerical listing of drillers and their addresses.

CSG (Casing Diameter in Inches) Casing diameters are shown to the nearest inch. Where several sizes of casings are used, the diameter of the upper casing only is given.

KIND OF WATER The following abbreviations were used to record the kind of water reported by the driller:

FR	Fresh
SA	Salty
SU	Sulphur
MN	Mineral

WATER FOUND FEET This is the distance or distances in feet below ground level at which the driller reported the occurrence of water.

STAT LVL FEET (Static Level in Feet) This is the distance to the water below ground level when the well is not being pumped. Static levels above ground are not given; the notation FLW, representing a flowing well, is given for this condition.

PUMP LVL FEET (Pumping Level in Feet) This is the distance to the water below ground level at the end of a pumping test or the start of a recovery test.

TEST RATE GPM (Pumping-Test Rate in Imperial Gallons per Minute) This is the rate at which the well was test-pumped. In some cases the stated rate is a recovery rate or the rate of flow of a flowing well.

TEST TIME HR/MN (Test Time in Hours and Minutes) It is the length of time during which the pumping or recovery test was conducted. Test times of 100 hours or greater are shown as 99 hours 59 minutes.

WATER USE The following abbreviations are used to describe water use:

Domestic	DO
Stock	ST
Irrigation	IR
Industrial	IN
Commercial	CO
Municipal	MU
Public Supply	PS
Cooling or Air Conditioning	CA

**OWNER/LOG**

The name of the original owner of the well is given on the top line.

The materials for each formation are described by standard abbreviations. They are listed in predominant order, i. e. the most common material first and other materials after. General colour qualifications are given where pertinent. The following examples illustrate the principle:

msnd gravel	- sand and gravel
grey clay fsnd grvl	- grey clay with fine sand and gravel
brown grvl csnd	- brown gravel and coarse sand

Material Abbreviations

Unknown	UNKN
Fill	FILL
Top Soil	TPSL
Muck	MUCK
Peat	PEAT
Clay	CLAY
Silt	SILT
Quicksand	QSND
Sand or Medium Sand	MSND
Fine Sand	FSND
Coarse Sand	CSND
Gravel	GRVL
Stones	STNS

Rock	ROCK

Colour Abbreviations

White	WHIT
Grey	GREY
Blue	BLUE
Green	GREN
Yellow	YLLW
Brown	BRWN
Red	RED
Black	BLCK

**DEPTHS IN  
FEET TO WHICH  
FORMATIONS  
EXTEND**

Each depth given represents the bottom of the formation which precedes the number. The last number for each well generally indicates the total depth of the well. Wells terminating at the bedrock/overburden interface are coded to show a one-foot penetration into the rock.

TABLE V  
OBSERVATION WELLS AND WATER LEVEL MEASUREMENTS  
NORTHERN ONTARIO  
1960 - 1969

District of Algoma

Observation Well No: 121  
Observer: Sault Ste. Marie PUC Personnel  
Location: City of Sault Ste. Marie, at the intersection  
First Avenue and Second Line, property of the  
Sault Ste. Marie Public Utilities Commission  
Type: Drilled  
Depth: 83.5 feet  
Aquifer: rock  
Data: From automatic Recorder charts  
Records commenced: Feb. 10, 1965  
Measuring Point: Recorder shelter platform 2.75 feet above manhole  
cover.

Water levels below land surface in feet

TABLE V  
District of Algoma

Observation Well No: 295  
Observer: Ontario Hydro Personnel  
Location: Wells Township, Con. VI, lot 6  
Rayner Generating Station  
Type: Drilled  
Depth: 51.3 feet  
Aquifer: Hard packed sand, cobble gravel  
Data: Courtesy of Ontario Hydro  
Records commenced: Dec. 15, 1952  
Elevation of Measuring Point: 729.95 which is 2.0 feet above land surface

Water levels below land surface in feet

1960

Observation Well No: 284  
 Observer: Ontario Hydro Personnel  
 Location: Matheson Twp., Con. I, lot 2  
 Type: Night Hawk Center  
 Depth: Drilled, piezometer  
 Aquifer: 44.4 feet  
 Data: Coarse sand  
 Records commenced: Courtesy of Ontario Hydro  
 Measuring point: Aug. 9, 1948  
 Top of well pipe, 2.40 feet above land surface

Water levels below land surface in feet  
1960

TABLE V

Observation Well No: 286  
 Observer: Ontario Hydro Personnel  
 Location: Shaw Twp., Con. V, lot 10  
 South Porcupine  
 Type: Drilled, piezometer  
 Depth: 31.1 feet  
 Aquifer: Coarse sand to fine gravel  
 Data: Courtesy of Ontario Hydro  
 Records commenced: Aug Aug. 9, 1948  
 Measuring point: Top of well pipe, 2.2 feet above land surface

## Water levels below land surface in feet

District of Kenora

Observation Well No: 208  
Observer: OWRG Personnel  
Location: Latitude North  $51^{\circ}51'$   
Longitude West  $89^{\circ}36'$   
Type: Drilled, piezometer  
Depth: 86.5 feet  
Aquifer: Fine and very fine sand with some silt  
Data: From automatic water level recorder charts  
Records commenced: Aug. 23, 1967  
Measuring point: Top of casing, 3 feet above land surface.

Observation Well No:

297

Observer:

Ontario Hydro Personnel

Location:

Ear Falls No. 4 Generating Station

Type:

Drilled, piezometer

Depth:

56 feet

Aquifer:

Gravel above rock surface at 56 feet

Data:

Courtesy of Ontario Hydro

Records commenced:

March 22, 1954

Measuring Point:

Top of casing, 1.6 feet above land surface

Water levels below land surface in feet

Observation Well No: 299  
 Observer: Ontario Hydro Personnel  
 Location: Lower Manitou Falls Generating Station Well No. 2  
 Type: Drilled, piezometer  
 Depth: 74.3 feet  
 Aquifer: very fine sand over rock at 71.3 feet  
 Data: Courtesy of Ontario Hydro  
 Records commenced: March 22, 1954  
 Measuring point: Top of casing, 4 feet above land surface
